Effects of elastase-induced emphysema on the synthesis and surface expression of the interleukin-4 receptor in lung macrophages. Exposure to the protease elastase can induce emphysema in rats and is characterized by macrophage activation. We have investigated the effects of elastase-induced emphysema on the synthesis and surface expression of the interleukin-4 receptor (IL-4R) in lung macrophages. Rats were exposed to 1 U of elastase for 12 weeks and control animals received PBS. Lung macrophages were purified and maintained in culture for 24 h. Cell activation was induced with lipopolysaccharide (LPS) or interferon-gamma (IFN-gamma). IL-4R mRNA was quantified by a competitive polymerase chain reaction assay. Surface expression of IL-4R was determined by FACS analysis. Elastase exposure increased the amount of IL-4R mRNA in cells stimulated with LPS or IFN-gamma. In contrast, total cellular IL-4R expression was not affected. This increase in IL-4R mRNA after elastase exposure was specific to the macrophages because IL-4R levels in bronchial epithelial cells were not affected. Increased IL-4R mRNA in lung macrophages could be related to the increased number of activated alveolar macrophages in emphysematous rats and/or increased production of IL-4 by macrophages in response to elastase exposure. In addition, this increase may be important for the regulation of inflammatory responses, such as the up-regulation of the IL-4R, in macrophages in emphysema.
